

THE ENERGY-CRITICAL NONLINEAR SCHRÖDINGER EQUATION ON A PRODUCT OF SPHERES

SEBASTIAN HERR AND NILS STRUNK

ABSTRACT. The Cauchy-problem for the energy-critical nonlinear Schrödinger equation is proved to be globally well-posed for small initial data in $H^1(\mathbb{S} \times \mathbb{S}^2)$. The proof is robust in the sense that depends only on a certain tri-linear estimate for free solutions, which is already known on the sphere and tori in $3d$, but verified here in the case $\mathbb{S} \times \mathbb{S}^2$.

1. INTRODUCTION

Burq–Gérard–Tzvetkov [3, 4, 5, 6] initiated a line of research on the well-posedness of nonlinear Schrödinger equations on compact manifolds, extending Bourgain’s results on tori [1, 2]. More precisely, on a given compact smooth d -dimensional Riemannian manifold (M, g) without boundary, the Cauchy-problem

$$\begin{cases} i\partial_t u + \Delta_g u = \pm |u|^{p-1} u \\ u|_{t=0} = u_0 \in H^s(M) \end{cases} \quad (1)$$

is studied, where $u_0 \in H^s(M)$ is given initially and the aim is to prove the existence and uniqueness of a solution $u \in C([0, T], H^s(M, \mathbb{C}))$ and its continuous dependence on u_0 . For sufficiently smooth solutions u the $L^2(M)$ -norm and the energy

$$E(u)(t) = \frac{1}{2} \int_M |\nabla u(t, x)|^2 dx \pm \frac{1}{p+1} \int_M |u(t, x)|^{p+1} dx$$

are conserved quantities.

On $M = \mathbb{R}^d$, solutions u of the equation (1) can be rescaled to solutions u_λ by setting

$$u_\lambda(t, x) = \lambda^{\frac{2}{p-1}} u(\lambda^2 t, \lambda x) \quad (\lambda > 0).$$

Key words and phrases. Nonlinear Schrödinger Equation, compact manifold, well-posedness.

The Sobolev semi-norm $\|\cdot\|_{\dot{H}^s(\mathbb{R}^d)}$ is invariant under this rescaling iff $s = s_c := \frac{d}{2} - \frac{2}{p-1}$ and we call the range $s > s_c$ sub-critical, $s < s_c$ super-critical and $s = s_c$ critical. In dimension $d = 3$, the quintic problem ($p = 5$) is called energy-critical since $s_c = 1$. In this case, well-posedness in the critical space $H^1(M)$ is a key ingredient in the analysis of global well-posedness: For small initial data this immediately follows from the conservation of the energy $E(u)$, and in the defocusing case it serves as a starting point for a proof of global well-posedness for large initial data.

Recently, first global results for (1) with $p = 5$ in the critical space $H^1(M)$ have been obtained on the specific manifolds $M = \mathbb{T}^3$ [11, 12, 18] and $M = \mathbb{S}^3$ [9, 15] with standard metrics. These critical results crucially rely on precise spectral information. In this paper, we consider the manifold $M = \mathbb{S} \times \mathbb{S}^2$ with the standard metric. With regard to concentration of eigenfunctions and localization of the spectrum of Δ_g this is an intermediate case between \mathbb{T}^3 and \mathbb{S}^3 , as explained in [5, p. 257, l. 26ff]. We consider this as a toy model for the central question concerning the critical well-posedness on arbitrary smooth compact Riemannian 3-manifold, cp. [5, p. 257, l. 31ff], as it forces us to unify some of the methods developed in [11, 9, 10]. On the other hand, its treatment requires new ideas, which we will point out below.

Precisely, we focus on the following Cauchy-problem

$$\begin{cases} i\partial_t u + \Delta_g u = \pm |u|^4 u \\ u|_{t=0} = u_0 \in H^s(\mathbb{S} \times \mathbb{S}^2) \end{cases} \quad (2)$$

and we will prove the following in the critical case $s = 1$:

Theorem 1.1. *The Cauchy problem (2) is globally well-posed for small initial data in $H^1(\mathbb{S} \times \mathbb{S}^2)$.*

As usual, this result includes the existence of (mild) solutions $u \in C(\mathbb{R}, H^1(\mathbb{S} \times \mathbb{S}^2))$, uniqueness in a certain subspace, continuous dependence on the initial data and persistence of higher initial H^s -regularity. Our methods also imply local well-posedness for arbitrarily large initial data in $H^1(\mathbb{S} \times \mathbb{S}^2)$ by standard arguments, which we omit. We refer the reader to [11, Theorem 1.1 and 1.2] for more explanations. In [5] the global well-posedness in H^1 has been proved in the sub-quintic case (i.e. $1 < p < 5$), see [5, Theorem 1] for a more complete statement and [5, Appendix A] for an ill-posedness result in a super-quintic case.

Generally speaking, the method of proof used here is similar to the cases $M = \mathbb{T}^3$ [11] and $M = \mathbb{S}^3$ [9] and ideas from [5, 6] are used in

order to deal with the fact that the spectral cluster estimates are not optimal on $M = \mathbb{S} \times \mathbb{S}^2$, see [5, Theorem 3 and Remark 2.1]. However, in the critical case the tri-linear estimate obtained in [5, Proposition 5.1] cannot be used because of the ε -loss, which essentially comes from the number-of-divisor-bound [5, Lemma 4.2]. The main new estimate is a critical tri-linear estimate for free solutions, see Proposition 2.6, which is also known for $M = \mathbb{T}^3$ (both rational [11, Proposition 3.5 and its proof, in particular (26)] and irrational [18, Proposition 4.1]) and $M = \mathbb{S}^3$ [9, Proposition 3.6 and its proof, see (20)]. From this estimate we derive the nonlinear estimate which is used for the Picard iteration argument, which is along the lines of [9]. We point out that this reduction of the well-posedness proof to critical tri-linear estimates for free solutions is independent of the specific manifold.

This paper is organized as follows: We conclude this section by introducing some notation. In Section 2 we prove the crucial tri-linear estimate for free solutions. In Section 3 we describe how the tri-linear estimate can be extended to a certain function space, which allows us to perform the standard Picard iteration argument.

Notation. In the following, we write $M := \mathbb{S} \times \mathbb{S}^2$. We use the same notation for the spectrum and the spectral projectors as in [5, Section 5]: The spectrum of $-\Delta = -\Delta_g$ is given by

$$\lambda_{m,n} = m^2 + n^2 + n, \quad (m, n) \in \mathbb{Z} \times \mathbb{N}_0.$$

We denote by $\Pi_n: L^2(\mathbb{S}^2) \rightarrow L^2(\mathbb{S}^2)$ the spectral projector onto spherical harmonics of degree n on \mathbb{S}^2 . For functions f on M we write $\mathbb{S} \times \mathbb{S}^2 \ni (\theta, \omega) \mapsto f(\theta, \omega)$. The m -th Fourier-coefficient of $f(\cdot, \omega)$ is defined by

$$\Theta_m f(\omega) := \frac{1}{2\pi} \int_0^{2\pi} f(\theta, \omega) e^{-im\theta} d\theta.$$

Hence, for $f \in L^2(M)$, we have

$$f(\theta, \omega) = \sum_{(m,n) \in \mathbb{Z} \times \mathbb{N}_0} e^{im\theta} \Pi_n \Theta_m(f)(\omega)$$

in the L^2 -sense. For dyadic $N = 1, 2, 4, \dots$ we define the projector

$$P_N f(\theta, \omega) = \sum_{\substack{(m,n) \in \mathbb{Z} \times \mathbb{N}_0: \\ N \leq \langle \lambda_{n,m} \rangle^{\frac{1}{2}} < 2N}} e^{im\theta} \Pi_n \Theta_m(f)(\omega),$$

where $\langle x \rangle = (1 + |x|^2)^{\frac{1}{2}}$, and $P_0 = \Pi_0 \Theta_0$. We define the usual L^2 -based Sobolev space $H^s(M) = (1 - \Delta_g)^{\frac{s}{2}} L^2(M)$, equipped with the norm

$$\|f\|_{H^s(M)} = \left(\sum_{(m,n) \in \mathbb{Z} \times \mathbb{N}_0} \langle \lambda_{m,n} \rangle^{2s} \|\Pi_n \Theta_m f\|_{L^2(M)}^2 \right)^{\frac{1}{2}}.$$

Due to L^2 -orthogonality we have

$$\|f\|_{H^s(M)}^2 \sim \sum_{N \geq 0} \langle N \rangle^{2s} \|P_N f\|_{L^2(M)}^2.$$

Here and in the sequel $\sum_{N \geq 0}$ indicates that we are summing over all $N = 0, 1, 2, 4, 8, \dots$

2. THE TRI-LINEAR ESTIMATE FOR FREE SOLUTIONS

In this section we are going to prove a new tri-linear Strichartz estimate for free solutions (Proposition 2.6). This proposition is an improvement of the tri-linear estimate [5, Proposition 5.1] of Burq–Gérard–Tzvetkov in the sense that it is critical.

We start this section collecting two known results, which we will rely on later. The following estimate on exponential sums is due to Bourgain [1] and was used to prove Strichartz estimates on the flat torus.

Lemma 2.1 (cp. [1, Formula (3.116)]). *Let $p > 4$, then for all $N \geq 0$, $a \in \ell^2(\mathbb{Z}^2)$, $z \in \mathbb{Z}^2$ and $\mathcal{S}_N \subseteq z + \{-N, \dots, N\}^2$ it holds that*

$$\left\| \sum_{n \in \mathcal{S}_N} e^{-i|n|^2 t} e^{in \cdot x} a_n \right\|_{L_{t,x}^p([0, 2\pi]^3)} \lesssim \langle N \rangle^{1 - \frac{4}{p}} \|a\|_{\ell^2}.$$

Proof/Reference. The desired estimate follows immediately from the Galilean transformation

$$x \cdot (n - z) - t|n - z|^2 = (x + 2tz) \cdot n - t|n|^2 - x \cdot z - t|z|^2,$$

as applied in [1, formulas (5.7)–(5.8)] and [11, Proposition 3.1], and from [1, formula (3.116)]. \square

We will also use the succeeding tri-linear spectral cluster estimate of Burq–Gérard–Tzvetkov, which is more generally valid for any compact smooth Riemannian manifold without boundary of dimension two.

Lemma 2.2 ([5, Theorem 3]). *For all integers $n_1 \geq n_2 \geq n_3 \geq 0$ and $f_1, f_2, f_3 \in L^2(\mathbb{S}^2)$ the following tri-linear estimate holds true*

$$\|\Pi_{n_1} f_1 \Pi_{n_2} f_2 \Pi_{n_3} f_3\|_{L^2(\mathbb{S}^2)} \lesssim (\langle n_1 \rangle \langle n_2 \rangle \langle n_3 \rangle)^{\frac{1}{4}} \prod_{j=1}^3 \|\Pi_{n_j} f_j\|_{L^2(\mathbb{S}^2)}.$$

Throughout this paper, let $\tau_0 = [0, 8\pi]$ be the considered time interval. For the purpose of proving Proposition 2.6, we will use following exponential sum estimate. The main idea is to reduce the estimate to Lemma 2.1.

Lemma 2.3. *Let $p > 4$. Then, for all $N \geq 0$, $a \in \ell^2(\mathbb{Z}^2)$, $z \in \mathbb{Z}^2$ and $\mathcal{S}_N \subseteq z + \{-N, \dots, N\}^2$ the estimate*

$$\left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i\lambda_{m,n}t} e^{im\theta} a_{m,n} \right\|_{L_{t,\theta}^p(\tau_0 \times \mathbb{S})} \lesssim \langle N \rangle^{1-\frac{3}{p}} \|a\|_{\ell^2}$$

holds true.

Proof. The case $N = 0$ is trivial and hence, we may assume $N \geq 1$. We first show that it suffices to replace $\lambda_{m,n}$ by $m^2 + n^2$. This follows easily by dilating the t variable by the factor 4 and modifying the sequence $a_{m,n}$. Hence, we are left to prove

$$\left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i(m^2+n^2)t} e^{im\theta} a_{m,n} \right\|_{L_{t,\theta}^p([0,2\pi]^2)} \lesssim N^{1-\frac{3}{p}} \|a\|_{\ell^2}.$$

In order to apply the exponential sum estimate of Lemma 2.1, we introduce another variable ν . Obviously, the left hand side is bounded by

$$\sup_{\nu \in [0,2\pi]} \left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i(m^2+n^2)t} e^{im\theta} e^{in\nu} a_{m,n} \right\|_{L_{t,\theta}^p([0,2\pi]^2)},$$

which can be further estimated by

$$\left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i(m^2+n^2)t} e^{im\theta} e^{in\nu} a_{m,n} \right\|_{L_{t,\theta}^p([0,2\pi]^2, L_\nu^\infty([0,2\pi]))}$$

using Minkowski's inequality. Sobolev's embedding in ν allows to bound this by a constant times

$$N^{\frac{1}{p}} \left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i(m^2+n^2)t} e^{im\theta} e^{in\nu} a_{m,n} \right\|_{L_{t,\theta,\nu}^p([0,2\pi]^3)}.$$

Finally, Lemma 2.1 implies the desired result. \square

Remark 1. One can even lower the power of integration over \mathbb{S} to 4, if the power of integration in time is raised to $p > \frac{16}{3}$: Let $p > \frac{16}{3}$, then, under the same assumptions on a , N , \mathcal{S}_N as in Lemma 2.3, the following estimate holds true:

$$\left\| \sum_{(m,n) \in \mathcal{S}_N} e^{-i\lambda_{m,n}t} e^{im\theta} a_{m,n} \right\|_{L_t^p(\tau_0, L_\theta^4(\mathbb{S}))} \lesssim \langle N \rangle^{\frac{3}{4} - \frac{2}{p}} \|a\|_{\ell^2}. \quad (3)$$

The proof is very similar to Bourgain's proof of Strichartz estimates on irrational tori [2, Proposition 1.1]. Note that in this argument the interval τ_0 does not have to be $[0, 8\pi]$. However, it seems that this estimate is not appropriate for studying local existence: We start with a tri-linear $L^2(\tau_0 \times M)$ estimate and proceed as in the proof of Proposition 2.6 until (5). Then, using Hölder's inequality to put the two functions with the highest frequencies to $L_t^{\frac{16}{3}+} L_\theta^4$ and thus the function with the lowest frequency, say N_3 , to $L_t^{8-} L_\theta^\infty$. We treat the latter term as follows: Applying Sobolev's embedding to bound it by the $L_t^{8-} L_\theta^4$ -norm gives a factor $N_3^{\frac{1}{4}}$. The exponential sum estimate (3) gives $N_3^{\frac{1}{2}-}$ and from the spectral cluster estimate we get another $N_3^{\frac{1}{4}}$ as in (5). All in all we obtain N_3^{1-} , and hence the power on the lowest frequency is too low to conclude local well-posedness. However, it is possible to increase the power on N_3 by considering bi-linear variants of (3). A similar strategy was used in [18], see Lemma 3.3 and the proof of Proposition 3.2.

The subsequent estimate will serve as a $L^\infty(\tau_0 \times \mathbb{S})$ estimate. It improves the previous lemma, because it takes additional smallness properties of the underlying point set $\mathcal{S}_{N,M}$ into account, which will be induced by almost orthogonality in time.

Lemma 2.4. *Let $a \in \ell^2(\mathbb{Z}^2)$, $N \geq M \geq 1$, and*

$$\mathcal{S}_{N,M} \subseteq \{(m, n) \in z + \{0, \dots, N\}^2 : \sqrt{\lambda_{m,n}} \in [b, b + M]\}$$

for some $z \in \mathbb{Z}^2$ and $b \in \mathbb{N}_0$. Then we have

$$\sum_{(m,n) \in \mathcal{S}_{N,M}} |a_{m,n}| \lesssim M^{\frac{1}{2}} N^{\frac{1}{2}} \|a\|_{\ell^2}.$$

Proof. By Cauchy-Schwarz, we only have to show $\#\mathcal{S}_{N,M} \lesssim MN$. Since

$$\#\mathcal{S}_{N,M} \leq \#\{(m, n) \in \tilde{z} + \{0, \dots, 2N\}^2 : \sqrt{m^2 + n^2} \in [2b, 2b + 4M]\},$$

where $\tilde{z} = 2z + (0, 1)$, we may assume $\lambda_{m,n} = m^2 + n^2$. The rest of the proof is motivated by [7, Section 2.7]. Consider all the lattice points in $\mathcal{S}_{N,M}$ as centers of unit squares with sides parallel to the coordinate

axes. Obviously, the number of lattice points in $\mathcal{S}_{N,M}$ equals the area of the union of these squares. The diagonal of the unit squares is $\sqrt{2}$. Consequently, the union of the squares is inside a $\frac{1}{\sqrt{2}}$ -neighborhood of $\mathcal{S}_{N,M}$. This neighborhood can be covered by an annulus of angle α , outer radius $R := 2b + 5M$ and inner radius $r := \max\{R - 6M, 0\}$, where $\alpha \in [0, 2\pi]$ is determined as follows: Since the point set is located in a cube of size N , the arc length of the annulus sector is bounded by $\sim N$. Thus $\alpha \sim \frac{N}{R}$, and we deduce that the area is bounded by

$$\frac{\alpha}{2}(R^2 - r^2) \lesssim \frac{N}{R}MR \lesssim MN.$$

□

Interpolating Lemma 2.3 and Lemma 2.4, we obtain an $L^p(\tau_0 \times \mathbb{S})$ estimate for $p > 4$ that takes additional smallness properties of the underlying point set into account as Lemma 2.4 does.

Corollary 2.5. *Let $p > 4$. Then, for all $\varepsilon > 0$, $\mathcal{S}_{N,M}$ as in Lemma 2.4, $N \geq M \geq 1$ and $a \in \ell^2(\mathbb{Z}^2)$ we have that*

$$\left\| \sum_{(m,n) \in \mathcal{S}_{N,M}} e^{-i\lambda_{m,n}t} e^{im\theta} a_{m,n} \right\|_{L^p_{t,\theta}(\tau_0 \times \mathbb{S})} \lesssim \left(\frac{N}{M}\right)^\varepsilon N^{\frac{1}{2}-\frac{1}{p}} M^{\frac{1}{2}-\frac{2}{p}} \|a\|_{\ell^2}.$$

Proof. We set $f(t, \theta) := |\sum_{(m,n) \in \mathcal{S}_{N,M}} e^{-i\lambda_{m,n}t} e^{im\theta} a_{m,n}|$ for brevity. The estimate is nontrivial only if $\varepsilon \leq \frac{p-4}{2p}$. Furthermore, we set $\varepsilon' = 2p\varepsilon > 0$ and $\vartheta = \frac{4+\varepsilon'}{p} \leq 1$. Then, Hölder's inequality, Lemma 2.3 and Lemma 2.4 imply

$$\|f\|_{L^p_{t,\theta}} = \|f^\vartheta f^{1-\vartheta}\|_{L^p_{t,\theta}} \leq \|f\|_{L^{4+\varepsilon'}_{t,\theta}}^\vartheta \|f\|_{L^\infty_{t,\theta}}^{1-\vartheta} \lesssim \left(\frac{N}{M}\right)^\varepsilon N^{\frac{1}{2}-\frac{1}{p}} M^{\frac{1}{2}-\frac{2}{p}} \|a\|_{\ell^2}.$$

□

Proposition 2.6. *There exists $\delta > 0$ such that for all $\phi_1, \phi_2, \phi_3 \in L^2(M)$ and dyadic numbers $N_1 \geq N_2 \geq N_3 \geq 0$ the estimate*

$$\begin{aligned} & \|P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3\|_{L^2(\tau_0 \times M)} \\ & \lesssim \left(\frac{\langle N_3 \rangle}{\langle N_1 \rangle} + \frac{1}{\langle N_2 \rangle} \right)^\delta \langle N_2 \rangle \langle N_3 \rangle \prod_{j=1}^3 \|\phi_j\|_{L^2(M)} \end{aligned}$$

holds true.

Proof. We only consider the nontrivial case $N_2 \geq 1$. The other case $N_3 \leq N_2 \leq 1$ can be treated as described in the beginning of the proof of [9, Proposition 3.6]. We will exploit almost orthogonality in the first three steps to show that we may assume the highest frequency to

be further localized. In the last step we will estimate the remaining tri-linear estimate using the foregoing results. First, we recall that for $t \in \tau_0$ and $(\theta, \omega) \in \mathbb{S} \times \mathbb{S}^2$

$$\begin{aligned} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega) \\ = \sum_{\mathcal{N}} \prod_{j=1}^3 e^{-i\lambda_{m_j, n_j} t} e^{im_j \theta} \Pi_{n_j} \Theta_{m_j} \phi_j(\omega), \end{aligned}$$

where $\mathcal{N} = \mathcal{N}_1 \times \mathcal{N}_2 \times \mathcal{N}_3$ and

$$\mathcal{N}_j = \{(m, n) \in \mathbb{Z} \times \mathbb{N}_0 : N_j \leq \langle \lambda_{m, n} \rangle^{\frac{1}{2}} < 2N_j\}, \quad j = 1, 2, 3. \quad (4)$$

In this proof $\sum_{\mathcal{N}}$ should be understood as $\sum_{(m_1, n_1, m_2, n_2, m_3, n_3) \in \mathcal{N}}$.

Step 1. Due to spatial almost orthogonality induced by the \mathbb{S} component, it suffices to prove the desired estimate in the case

$$P_{\mathcal{R}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3,$$

where $\mathcal{R} \subseteq [b, b + N_2] \times [0, 2N_1]$ for some $b \in \mathbb{Z}$. We spell out more details in the next step.

Step 2. Now, we use almost orthogonality that comes from the \mathbb{S}^2 component. It is a well-known fact, that the product of a spherical harmonic of degree n with another of degree m can be expanded in terms of spherical harmonics of degree less or equal to $n + m$. Another well-known fact about spherical harmonics is that two spherical harmonics are orthogonal in $L^2(\mathbb{S}^d)$, $d \in \mathbb{N}$, if they are of different degree. We finally remark, that complex conjugation does not change the degree of a spherical harmonic. Details may be found in e.g. [17, Section VI.2]. Now, we prove that it suffices to consider the case, where n_1 is located in an interval of the size of the second highest frequency, N_2 . To that purpose, we define the following partition of \mathbb{N}_0 :

$$\mathbb{N}_0 = \dot{\bigcup}_{k \in \mathbb{N}_0} I_k \quad \text{where} \quad I_k = [kN_2, (k+1)N_2).$$

We claim that for fixed $\theta \in \mathbb{S}$ and $t \in \tau_0$ it holds that

$$\begin{aligned} & \|P_{\mathcal{R}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta)\|_{L^2(\mathbb{S}^2)}^2 \\ & \sim \sum_{k \in \mathbb{N}_0} \|P_{\mathcal{R}_k} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta)\|_{L^2(\mathbb{S}^2)}^2, \end{aligned}$$

where $\mathcal{R}_k = \mathcal{R} \cap (\mathbb{Z} \times I_k)$. Let $k, \tilde{k} \in \mathbb{N}_0$, then

$$\begin{aligned} & \langle P_{\mathcal{R}_k} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta), \\ & P_{\mathcal{R}_{\tilde{k}}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta) \rangle_{L^2(\mathbb{S}^2)} \\ &= \sum_{\substack{\mathcal{R}_k \times \mathcal{N}_2 \times \mathcal{N}_3, \\ \mathcal{R}_{\tilde{k}} \times \mathcal{N}_2 \times \mathcal{N}_3}} I_{\mathcal{R}_k}^{\mathcal{R}_{\tilde{k}}} \prod_{j=1}^3 e^{-i(\lambda_{m_j, n_j} - \lambda_{\tilde{m}_j, \tilde{n}_j})t} e^{i(m_j - \tilde{m}_j)\theta}, \end{aligned}$$

where

$$I_{\mathcal{R}_k}^{\mathcal{R}_{\tilde{k}}} = \int_{\mathbb{S}^2} \prod_{j=1}^3 \Pi_{n_j} \Theta_{m_j} \phi_j(\omega) \overline{\Pi_{\tilde{n}_j} \Theta_{\tilde{m}_j} \phi_j(\omega)} d\omega.$$

Without loss of generality we may assume $n_1 > \tilde{n}_1$. Then

$$Y := \overline{\Pi_{\tilde{n}_1} \Theta_{\tilde{m}_1} \phi_1} \prod_{j=2}^3 \Pi_{n_j} \Theta_{m_j} \phi_j \overline{\Pi_{\tilde{n}_j} \Theta_{\tilde{m}_j} \phi_j} \in L^2(\mathbb{S}^2)$$

can be expanded in terms of spherical harmonics of degree less or equal to $\tilde{n}_1 + 8N_2$. Hence, if $|k - \tilde{k}| \gg 1$, then

$$I_{\mathcal{R}_k}^{\mathcal{R}_{\tilde{k}}} = \langle \Pi_{n_1} \Theta_{m_1} \phi_1, \overline{Y} \rangle_{L^2(\mathbb{S}^2)} = 0.$$

Step 3. Using almost orthogonality in time, we may gain a small power of $M := \max\{\frac{N_2^2}{N_1}, 1\}$. Similar ideas have been used in the proofs of [11, Proposition 3.5] and [9, Proposition 3.6], for instance. We define the partition

$$\mathbb{N}_0 = \bigcup_{\ell \in \mathbb{N}_0} J_\ell \quad \text{where} \quad J_\ell = [\ell M, (\ell + 1)M).$$

We show that we may assume $\sqrt{\lambda_{m_1, n_1}}$ to vary in an interval of length M : Fix $(\theta, \omega) \in \mathbb{S} \times \mathbb{S}^2$ and set

$$\mathcal{S}_{k, \ell} = \{(m_1, n_1) \in \mathcal{R}_k : \sqrt{\lambda_{m_1, n_1}} \in J_\ell\}, \quad k, \ell \in \mathbb{N}_0,$$

then we claim that

$$\begin{aligned} & \|P_{\mathcal{R}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega)\|_{L_t^2(\tau_0)}^2 \\ & \sim \sum_{k, \ell \in \mathbb{N}_0} \|P_{\mathcal{S}_{k, \ell}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega)\|_{L_t^2(\tau_0)}^2. \end{aligned}$$

We consider the inner product

$$\begin{aligned} & \left\langle P_{\mathcal{S}_{k,\ell}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega), \right. \\ & \quad \left. P_{\mathcal{S}_{k,\tilde{\ell}}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega) \right\rangle_{L_t^2(\tau_0)} \\ &= \sum_{\substack{\mathcal{S}_{k,\ell} \times \mathcal{N}_2 \times \mathcal{N}_3, \\ \mathcal{S}_{k,\tilde{\ell}} \times \mathcal{N}_2 \times \mathcal{N}_3}} I_{\mathcal{S}_{k,\ell}}^{\mathcal{S}_{k,\tilde{\ell}}} \prod_{j=1}^3 e^{i(m_j - \tilde{m}_j)\theta} \Pi_{n_j} \Theta_{m_j} \phi_j(\omega) \overline{\Pi_{\tilde{n}_j} \Theta_{\tilde{m}_j} \phi_j(\omega)}, \end{aligned}$$

where $I_{\mathcal{S}_{k,\ell}}^{\mathcal{S}_{k,\tilde{\ell}}}$ is defined by

$$I_{\mathcal{S}_{k,\ell}}^{\mathcal{S}_{k,\tilde{\ell}}} = \int_{\tau_0} e^{-i(\lambda_{m_1, n_1} + \lambda_{m_2, n_2} + \lambda_{m_3, n_3} - \lambda_{\tilde{m}_1, \tilde{n}_1} - \lambda_{\tilde{m}_2, \tilde{n}_2} - \lambda_{\tilde{m}_3, \tilde{n}_3})t} dt.$$

Assuming $|\ell - \tilde{\ell}| \gg 1$, we may estimate the modulus of the phase from below by

$$\left| \left(\sqrt{\lambda_{m_1, n_1}} + \sqrt{\lambda_{\tilde{m}_1, \tilde{n}_1}} \right) \left(\sqrt{\lambda_{m_1, n_1}} - \sqrt{\lambda_{\tilde{m}_1, \tilde{n}_1}} \right) \right| - 16N_2^2 \gtrsim |\ell - \tilde{\ell}| N_2^2,$$

hence $I_{\mathcal{S}_{k,\ell}}^{\mathcal{S}_{k,\tilde{\ell}}} = 0$.

Step 4. Thanks to the first three steps, we may replace $P_{N_1} e^{it\Delta} \phi_1$ by $P_{\mathcal{S}} P_{N_1} e^{it\Delta} \phi_1$, where $\mathcal{S} = \mathcal{S}_{k,\ell}$ for some $k, \ell \in N_0$. Recall that for $t \in \tau_0$ and $(\theta, \omega) \in \mathbb{S} \times \mathbb{S}^2$

$$\begin{aligned} & P_{\mathcal{S}} P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3(\theta, \omega) \\ &= \sum_{\mathcal{M}} \prod_{j=1}^3 e^{-i\lambda_{m_j, n_j} t} e^{im_j \theta} \Pi_{n_j} \Theta_{m_j} \phi_j(\omega), \end{aligned}$$

where $\mathcal{M} := \mathcal{S} \times \mathcal{N}_2 \times \mathcal{N}_3$ and \mathcal{N}_j , $j = 2, 3$, are defined in (4). The next step is a nice way to treat the $L^2(\mathbb{S}^2)$ -norm separately without losing oscillations in the \mathbb{S} component and in time. Note that this was also used by Burq–Gérard–Tzvetkov in the proof of [5, Proposition 5.1]. Plancherel’s identity with respect to t and θ and the triangle inequality

for the $L^2(\mathbb{S}^2)$ norm yield

$$\begin{aligned}
& \|P_S P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3\|_{L^2(\tau_0 \times M)}^2 \\
& \leq \sum_{\tau \in \mathbb{N}_0, \xi \in \mathbb{Z}} \left\| \sum_{\substack{(m_1, n_1, m_2, n_2, m_3, n_3) \in \mathcal{M}: \\ \tau = \lambda_{m_1, n_1} + \lambda_{m_2, n_2} + \lambda_{m_3, n_3}, \\ \xi = m_1 + m_2 + m_3}} \prod_{j=1}^3 \Pi_{n_j} \Theta_{m_j} \phi_j \right\|_{L^2(\mathbb{S}^2)}^2 \\
& \leq \sum_{\tau \in \mathbb{N}_0, \xi \in \mathbb{Z}} \left[\sum_{\substack{(m_1, n_1, m_2, n_2, m_3, n_3) \in \mathcal{M}: \\ \tau = \lambda_{m_1, n_1} + \lambda_{m_2, n_2} + \lambda_{m_3, n_3}, \\ \xi = m_1 + m_2 + m_3}} \left\| \prod_{j=1}^3 \Pi_{n_j} \Theta_{m_j} \phi_j \right\|_{L^2(\mathbb{S}^2)} \right]^2.
\end{aligned}$$

In contrast to [5, Proposition 5.1], we do not try to estimate the number of terms of the inner sum, but we go back to the physical space: We set $a_{m_j, n_j}^{(j)} := \|\Pi_{n_j} \Theta_{m_j} \phi_j\|_{L^2(\mathbb{S}^2)}$ for $j = 1, 2, 3$ and apply Lemma 2.2 as well as Plancherel's identity with respect to t and θ to obtain

$$\begin{aligned}
& \|P_S P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3\|_{L^2(\tau_0 \times M)}^2 \\
& \lesssim (N_2 N_3)^{\frac{1}{2}} \sum_{\tau \in \mathbb{N}_0, \xi \in \mathbb{Z}} \left(\sum_{\substack{(m_1, n_1, m_2, n_2, m_3, n_3) \in \mathcal{M}: \\ \tau = \lambda_{m_1, n_1} + \lambda_{m_2, n_2} + \lambda_{m_3, n_3}, \\ \xi = m_1 + m_2 + m_3}} \prod_{j=1}^3 a_{m_j, n_j}^{(j)} \right)^2 \quad (5) \\
& \lesssim (N_2 N_3)^{\frac{1}{2}} \left\| \sum_{\mathcal{M}} \prod_{j=1}^3 e^{-i\lambda_{m_j, n_j} t} e^{im_j \theta} a_{m_j, n_j}^{(j)} \right\|_{L_{t, \theta}^2(\tau_0 \times \mathbb{S})}^2.
\end{aligned}$$

Choose $p_1 > 4$ and $12 < p_3 < \infty$ and let $p_2 > 4$ be defined via the Hölder relation $\frac{1}{2} = \frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3}$. We apply Hölder's estimate to obtain

$$\begin{aligned}
& \|P_S P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3\|_{L^2(\tau_0 \times M)} \\
& \leq (N_2 N_3)^{\frac{1}{4}} \left\| \sum_{(m_1, n_1) \in \mathcal{S}} e^{-i\lambda_{m_1, n_1} t} e^{im_1 \theta} a_{m_1, n_1}^{(1)} \right\|_{L_{t, \theta}^{p_1}(\tau_0 \times \mathbb{S})} \\
& \quad \times \prod_{j=2}^3 \left\| \sum_{(m_j, n_j) \in \mathcal{N}_j} e^{-i\lambda_{m_j, n_j} t} e^{im_j \theta} a_{m_j, n_j}^{(j)} \right\|_{L_{t, \theta}^{p_j}(\tau_0 \times \mathbb{S})}.
\end{aligned}$$

We estimate the first term using Corollary 2.5 and the other terms using Lemma 2.3. Then, we obtain for all $\varepsilon > 0$

$$\begin{aligned} & \|P_S P_{N_1} e^{it\Delta} \phi_1 P_{N_2} e^{it\Delta} \phi_2 P_{N_3} e^{it\Delta} \phi_3\|_{L^2(\tau_0 \times M)} \\ & \lesssim (N_2 N_3)^{\frac{1}{4}} M^{\frac{1}{2} - \frac{2}{p_1} - \varepsilon} N_2^{\frac{3}{2} - \frac{1}{p_1} - \frac{3}{p_2} + \varepsilon} N_3^{1 - \frac{3}{p_3}} \prod_{j=1}^3 \|\phi_j\|_{L^2(M)} \\ & \lesssim \left(\frac{N_2}{N_1} + \frac{1}{N_2} \right)^{\frac{1}{2} - \frac{2}{p_1} - \varepsilon} N_2^{\frac{3}{4} + \frac{3}{p_3}} N_3^{\frac{5}{4} - \frac{3}{p_3}} \prod_{j=1}^3 \|\phi_j\|_{L^2(M)}. \end{aligned}$$

Since $p_1 > 4$ and $p_3 > 12$, this implies the desired estimate provided $\varepsilon > 0$ is sufficiently small. \square

3. FUNCTION SPACES AND THE NONLINEAR ESTIMATE

We briefly recall the function spaces U^p and V^p introduced by Koch–Tataru [13], which have been successfully employed in the context of critical dispersive equations. We refer the reader to [8] or [14] for more details and to [11, Section 2], [9, Section 2], and [10, Section 2] for this machinery in the context of the nonlinear Schrödinger equations on manifolds.

Definition 3.1. Let $1 \leq p < \infty$.

(i) A step function $a: \mathbb{R} \rightarrow L^2$ is called a U^p -atom, if

$$a(t) = \sum_{k=1}^K \chi_{[t_{k-1}, t_k)} a_k, \quad \sum_{k=0}^{K-1} \|a_k\|_{L^2}^p = 1$$

for a partition $-\infty < t_0 < \dots < t_K \leq \infty$. The space U^p is defined as the corresponding atomic space.

(ii) The space V^p is the space of right-continuous functions $v: \mathbb{R} \rightarrow L^2$ such that

$$\|v\|_{V^p}^p = \sup_{-\infty < t_0 < \dots < t_K \leq \infty} \sum_{k=1}^K \|v(t_k) - v(t_{k-1})\|_{L^2}^p < +\infty$$

with the convention $v(+\infty) := 0$, and in addition we require $\lim_{t \rightarrow -\infty} v(t) = 0$.

We use the resolution spaces as defined in [9, Definition 2.3]:

Definition 3.2. Let $s \in \mathbb{R}$.

- (i) X^s is defined as the space of all $u: \mathbb{R} \rightarrow H^s(M)$ such that $e^{-it\Delta}P_N u \in U^2$ for all dyadic $N \geq 0$ and

$$\|u\|_{X^s} := \left(\sum_{N \geq 0} \langle N \rangle^{2s} \|e^{-it\Delta}P_N u\|_{U^2}^2 \right)^{\frac{1}{2}} < +\infty.$$

- (ii) Y^s is defined as the space of all $u: \mathbb{R} \rightarrow H^s(M)$ such that $e^{-it\Delta}P_N u \in V^2$ for all dyadic $N \geq 0$ and

$$\|u\|_{Y^s} := \left(\sum_{N \geq 0} \langle N \rangle^{2s} \|e^{-it\Delta}P_N u\|_{V^2}^2 \right)^{\frac{1}{2}} < +\infty.$$

- (iii) For an interval $\tau \subset \mathbb{R}$ we denote by $X^s(\tau)$ resp. $Y^s(\tau)$ the restriction space.

Next, we show how Proposition 2.6 implies Theorem 1.1. We remark that this derivation does not depend on the specifics of $M = \mathbb{S} \times \mathbb{S}^2$, it is similar to [9, Corollary 3.7], cp. also [11, 10] for corresponding arguments using unit scales instead of dyadic scales.

Proposition 3.3. *There exists $\delta > 0$ such that for all dyadic numbers $N_1 \geq N_2 \geq N_3 \geq 0$ and $P_{N_j} u_j \in Y^0$ ($j = 1, 2, 3$) the following holds true*

$$\begin{aligned} \|P_{N_1} \tilde{u}_1 P_{N_2} \tilde{u}_2 P_{N_3} \tilde{u}_3\|_{L^2(\tau_0 \times M)} \\ \lesssim \left(\frac{\langle N_3 \rangle}{\langle N_1 \rangle} + \frac{1}{\langle N_2 \rangle} \right)^\delta \langle N_2 \rangle \langle N_3 \rangle \prod_{j=1}^3 \|P_{N_j} u_j\|_{Y^0}, \end{aligned} \quad (6)$$

where \tilde{u}_j denotes either u_j or $\overline{u_j}$.

Proof. Since the L^2 -norm on the left hand side does not change under complex conjugation of any factor, we may ignore possible complex conjugations.

Step 1. We start proving estimate (6) with Y^0 replaced by X^0 . In this case, it suffices to consider U^2 -atoms a_1, a_2, a_3 , given as

$$P_{N_j} a_j = \sum_{k=1}^{K_j} \chi_{I_{k,j}} e^{it\Delta} P_{N_j} \phi_{k,j}, \quad \sum_{k=0}^{K_j-1} \|\phi_{k,j}\|_{L^2}^2 = 1,$$

with pairwise disjoint right-open intervals $I_{1,j}, I_{2,j}, \dots, I_{K_j,j}$. Now,

$$\|P_{N_1} a_1 P_{N_2} a_2 P_{N_3} a_3\|_{L^2}^2 \leq \sum_{k_1, k_2, k_3} \|e^{it\Delta} P_{N_1} \phi_{k_1,1} e^{it\Delta} P_{N_2} \phi_{k_2,2} e^{it\Delta} P_{N_3} \phi_{k_3,3}\|_{L^2}^2$$

and Proposition 2.6 implies

$$\|P_{N_1} a_1 P_{N_2} a_2 P_{N_3} a_3\|_{L^2} \leq C_\delta(N_1, N_2, N_3),$$

with the constant $C_\delta(N_1, N_2, N_3)$ from Proposition 2.6, which yields

$$\|P_{N_1}u_1P_{N_2}u_2P_{N_3}u_3\|_{L^2} \leq C_\delta(N_1, N_2, N_3) \prod_{j=1}^3 \|e^{-it\Delta}P_{N_j}u_j\|_{U^2}. \quad (7)$$

Step 2. Now, choosing $N_1 = N_2 = N_3 = N$ and $\phi_1 = \phi_2 = \phi_3$ in Proposition 2.6, we obtain

$$\|P_N e^{it\Delta} \phi\|_{L^6} \lesssim \langle N \rangle^{\frac{2}{3}} \|P_N \phi\|_{L^2}.$$

As above, the estimate carries over to U^6 -atoms, hence

$$\|P_N u\|_{L^6} \lesssim \langle N \rangle^{\frac{2}{3}} \|e^{-it\Delta} P_N u\|_{U^6}, \quad (8)$$

and for general $N_1 \geq N_2 \geq N_3 \geq 0$, by Hölder's inequality,

$$\|P_{N_1}u_1P_{N_2}u_2P_{N_3}u_3\|_{L^2} \lesssim (\langle N_1 \rangle \langle N_2 \rangle \langle N_3 \rangle)^{\frac{2}{3}} \prod_{j=1}^3 \|e^{-it\Delta} P_{N_j} u_j\|_{U^6}. \quad (9)$$

Also, by Hölder's inequality and the Sobolev embedding, see [16, formula (2.6)] and [9, Lemma 3.4], we obtain

$$\begin{aligned} \|P_{N_1}u_1P_{N_2}u_2P_{N_3}u_3\|_{L^2} &\leq |\tau_0|^{\frac{1}{2}} \|P_{N_1}u_1\|_{L_t^\infty L_x^2} \|P_{N_2}u_2\|_{L^\infty} \|P_{N_3}u_3\|_{L^\infty} \\ &\lesssim (\langle N_2 \rangle \langle N_3 \rangle)^{\frac{3}{2}} \prod_{j=1}^3 \|P_{N_j}u_j\|_{L_t^\infty L_x^2}. \end{aligned}$$

For any $p \geq 1$, using $U^p \hookrightarrow L_t^\infty L_x^2$, we obtain the bound

$$\|P_{N_1}u_1P_{N_2}u_2P_{N_3}u_3\|_{L^2} \lesssim (\langle N_2 \rangle \langle N_3 \rangle)^{\frac{3}{2}} \prod_{j=1}^3 \|e^{-it\Delta} P_{N_j} u_j\|_{U^p}, \quad (10)$$

which is not scale invariant, but the constant does not depend on $\langle N_1 \rangle$.

Step 3. We distinguish two cases:

Case a) $\langle N_2 \rangle \langle N_3 \rangle > \langle N_1 \rangle$. In this case, we interpolate (7) and (9) using [9, Lemma 2.4] and obtain

$$\|P_{N_1}u_1P_{N_2}u_2P_{N_3}u_3\|_{L^2} \lesssim A_\delta \prod_{j=1}^3 \|e^{-it\Delta} P_{N_j} u_j\|_{V^2},$$

where

$$\begin{aligned} A_\delta &= C_\delta(N_1, N_2, N_3) \left(\ln \frac{(\langle N_1 \rangle \langle N_2 \rangle \langle N_3 \rangle)^{\frac{2}{3}}}{C_\delta(N_1, N_2, N_3)} + 1 \right)^3 \\ &\lesssim C_\delta(N_1, N_2, N_3) \left(\ln \frac{\langle N_1 \rangle}{\langle N_3 \rangle} + 1 \right)^3 \lesssim C_{\delta'}(N_1, N_2, N_3) \end{aligned}$$

for any $\delta' < \delta$.

Case b) $\langle N_2 \rangle \langle N_3 \rangle \leq \langle N_1 \rangle$. Now, we interpolate (7) and (10) using [9, Lemma 2.4] and obtain

$$\|P_{N_1} u_1 P_{N_2} u_2 P_{N_3} u_3\|_{L^2} \lesssim B_\delta \prod_{j=1}^3 \|e^{-it\Delta} P_{N_j} u_j\|_{V^2},$$

where

$$\begin{aligned} B_\delta &= C_\delta(N_1, N_2, N_3) \left(\ln \frac{(\langle N_2 \rangle \langle N_3 \rangle)^{\frac{3}{2}}}{C_\delta(N_1, N_2, N_3)} + 1 \right)^3 \\ &\lesssim C_\delta(N_1, N_2, N_3) (\ln \langle N_2 \rangle + 1)^3 \lesssim C_{\delta'}(N_1, N_2, N_3) \end{aligned}$$

for any $\delta' < \delta$, and the claim follows. \square

In order to prove Theorem 1.1 we intend to solve the integral equation

$$u(t) = e^{it\Delta} u_0 \mp i\mathcal{I}(|u|^4 u)(t), \quad \mathcal{I}(f)(t) := \int_0^t e^{i(t-s)\Delta} f(s) ds, \quad (11)$$

for $u_0 \in H^1(M)$ by invoking the contraction mapping principle in a small closed ball in the space $X^1(\tau_0) \subset C(\tau_0, H^1(M))$. For this, it suffices to provide the following estimate, cp. [9, Proposition 4.2] and [11, Proposition 4.1]:

Proposition 3.4. *For all $u, v \in X^1(\tau_0)$,*

$$\|\mathcal{I}(|u|^4 u) - \mathcal{I}(|v|^4 v)\|_{X^1(\tau_0)} \lesssim (\|u\|_{X^1(\tau_0)}^4 + \|v\|_{X^1(\tau_0)}^4) \|u - v\|_{X^1(\tau_0)}. \quad (12)$$

Proof (sketch). Due to the polynomial structure of the nonlinearity it suffices to prove an estimate for $\mathcal{I}(\prod_{j=1}^5 \tilde{u}_j)$ where \tilde{u}_j denotes either u_j or $\overline{u_j}$. This is treated exactly as in [9, Proposition 4.2] (and [11, Proposition 4.1]), where Proposition 3.3 is the replacement for [9, Corollary 3.7]. Note that the contribution Σ_2 in [9, pp. 1285–1287] is void in the case $M = \mathbb{S} \times \mathbb{S}^2$ (but [9, Lemmas 3.3 and 3.4] hold true on any smooth compact Riemannian 3-manifold M). \square

To conclude the proof of Theorem 1.1 one can iterate the local well-posedness to arbitrarily large time intervals $[0, T)$ by using the conservation of the mass and the energy, see [11, pp. 344–347] for more details.
